Abstract

Research Question/Issue: This is a study of the relationship between business group ownership and constituent firms' adoption of Anglo-American shareholder value governance in African firms at the undertaking of an initial public offering (IPO).

Research Findings/Insights: We find business group ownership to be associated with lower Anglo-American corporate governance adoption by constituent firms. However, this association is reversed in the institutional context of higher tribalism, while correspondingly being exacerbated in the context of lower tribalism.

Theoretical/Academic Implications: We theorize that the influence of business group ownership on firms' adoption of Anglo-American corporate governance is better understood when considering the institutional context. We highlight how informal cultural institutions are heterogeneous and thus shape the indigenous political economy and impact business groups. Specifically, we argue institutional contexts with higher tribalism are associated with more in-group favoritism and nepotism. This association makes it critical for business group constituent firms to escape the constraints of the political economy of tribalism when attracting outside funding, leading to a higher inclination to adopt Anglo-American governance. Contrastingly, in lower tribalism contexts, there is more universal trust across societies and an increased availability of domestic funding.

Practitioner/Policy Implications: Given the proliferation of business group ownership within economies worldwide, the study provides a useful framework with which to gauge the influence of business group ownership on a constituent firm's adoption of Anglo-American governance best practice. In particular, the study emphasizes that the interdependence of formal institutional architecture and tribalism—both fundamentally associated with the demographic shape and with the incentive structures embedded within the underlying national political economy—calls for careful considerations when making national corporate governance recommendations.

1 | INTRODUCTION

Emerging economies are characterized by institutional voids and an accompanying reliance on social networks and business groups (BGs) as essential elements of informal, internalized intermediation of resources (Ge et al., 2019; Tajeddin & Carney, 2019). While networks and BGs are distinctively shaped by the indigenous cultural context from which they originate and hold cognitive legitimacy (Suchman, 1995), the need for expansion and growth in BGs stimulates their seeking supplementary external funding (Masulis et al., 2011). This leads to a juncture occurring between the legitimacy sought and resources procured from opaque indigenous networks, versus the increased legitimacy from and conformity with international capital market norms, essential in external funding (Luo et al., 2009). However, a largely overlooked issue in the literature is that the underlying “national” cultural configuration of societies is rarely uniform, but rather shaped by varying degrees of socio-cultural fragmentation, recently labelled tribalism (Hearn & Filatotchev, 2019). Therefore, we explore the impact of BG ownership on constituent firms' adoption of Anglo-American shareholder value corporate governance and how this relation is moderated by the level of tribalism in the country.

Our theoretical approach is centered on the institutional perspective that accommodates the contextual embeddedness of economic actors and firms within underlying social frameworks (Filatotchev et al., 2018). This perspective is of particular importance given our focus on BGs, where these sociologically emanate from within the cultural fabric of society and are reflected by a coalescence of constituent firms centered on a socially cohesive entity such as an extended family, but also on corporate, state, and individual business interests (Khanna & Palepu, 2000). In our empirical analysis, we focus on Africa, where the latter are exemplified by Nigeria's *Dangote* and Egypt's *Sawiris* extended family groups (The Economist, 2019). In order to attain expansionary and/or growth goals, BGs necessarily require supplementary external capital, with this leading to a trade-off in the adoption of two opposing forms of corporate governance—one associated with the indigenous socio-cultural context and the other with international capital market norms. Corporate governance in the former context is typified by opacity and the dominance of insider welfare and property rights protection, usually in the form of culturally imbued relational contracting. Contrastingly, in the latter context, minority welfare and property rights protection are emphasized, as enshrined in the shareholder value corporate governance model (Aguilera & Jackson, 2010). Our theoretical model implicitly assumes the transition between the two frameworks as being mirrored by a continuum in the level of adoption of shareholder value governance elements by individual constituent firms. In this way, we capture the role played by the change in the institutional framework. We also capture the dominant actors embedded in this framework, from which BG-controlled constituent firms seek legitimacy and conformity in their corporate governance arrangements. Our emphasis on contextual embeddedness and legitimacy underscores our first theoretical contribution, which differentiates our approach from that of

agency-based and neoclassical studies. The agency-based studies are restricted in considering institutions as a “thin veil” in contractual enforcement (e.g., Aguilera & Jackson, 2010; Jensen & Meckling, 1976), while neoclassical studies are constrained by their singular view emphasizing convergence of firms' governance (e.g., Coffee, 2001) to a dominant Anglo-American shareholder value model.

We draw upon the concept of tribalism and highlight its relevance to corporate governance research on emerging market firms. Specifically, we utilize a novel index that captures tribalism as a continuum (Jacobson & Deckard, 2012), thereby overcoming shortfalls in prior typological categorizations of national institutional frameworks based on variations of this phenomenon (Fainshmidt et al., 2018). Our definition of tribalism relates to the concept of ethno-cultural fragmentation that leads to powerful institutionalized within-group social cohesion and loyalties, where these are often controversially associated with varying degrees of favoritism and nepotism (Arenke et al., 2022). Tribal or clan-based lineages are common worldwide and especially within emerging and developing economies (Greif & Tabellini, 2010). Countries across Africa in particular, but also in Asia and the Middle East, exhibit often high and varying degrees of tribalism, where related institutions are subverted beneath modern and essentially incongruous state bureaucracy (Nunn & Wantchekon, 2011). While this pattern reflects institutionalized fault lines within many emerging economies, it is representative of a powerful phenomenon in terms of societal organization. The role of tribalism is almost entirely overlooked in studies on culture and corporate governance (Hooghiemstra et al., 2014; Mintz, 2005), where aggregated “national” cultures are considered determinants of Anglo-American shareholder value corporate governance adoption. Moreover, existing studies mostly focus on the more static nature of ethnic, linguistic, and religious fractionalization (Alesina et al., 2003). Thus, past research captures fragmentation within a given society but overlooks a deeper appreciation of the institutionalized influences arising from this fragmentation.

Our empirical analysis is based on a hand-collected dataset of 189 firms that underwent initial public offerings (IPOs) in 22 markets across the African continent between January 2000 and August 2016. We find that the degree of tribalism significantly moderates the negative relation between the BG's ownership of a constituent firm and the degree of adoption of Anglo-American corporate governance practice. Our study makes two methodological contributions. The first is our adaptation of the New York Stock Exchange manuals' governance criteria (NYSE, 2016) to form a firm-level Anglo-American shareholder value index appropriate for emerging market firms. The new index is adjusted for data availability and institutional limitations on corporate governance. The adjustment implies that the index is simple to construct, tractable, and has universal applicability. The second methodological contribution is our novel application of a tribalism index (Jacobson & Deckard, 2012), which addresses shortcomings associated with static fractionalization metrics by providing a more dynamic measure. The index also considers interactions between ethnic groups and the institutionalized means of operationalizing culture

embedded within relational contracting systems. Our tribalism index provides a plausible means to account for informal diversity within national frontiers, thereby addressing some of the shortcomings of traditional aggregate measures of “national culture” (Tung & Stahl, 2018).

Our study proceeds in the next section by outlining the theory and hypotheses. Section 3 outlines data considerations. Section 4 focusses on empirical methods, while Section 5 presents the empirical results. The paper ends with concluding remarks and policy recommendations.

2 | THEORETICAL BACKGROUND AND HYPOTHESIS DEVELOPMENT

Our theoretical model focusses on how the level of BG ownership in a constituent firm determines its overall corporate governance. Specifically, we argue that an emerging economy firm can conform to one of two corporate governance models: an opaque indigenous model or an Anglo-American model. We further extend our theorization on alternative corporate governance models by addressing the moderating impact of the informal institutional framework in the form of tribalism.

Central to our argumentation is the concept of emerging economies being dominated by dense, overlapping social networks (Armitage et al., 2017), which almost wholly subsume all social and economic activity. Moreover, this myriad of social networks hosts BGs alongside powerful local actors, whose interrelationships both between one another and within themselves are governed by relational contracting schemas (Barnett et al., 2013). Importantly, all these social networks have common sociological origins (Bizer & Hamann, 2015), deep within the cultural fabric of the indigenous society. Consequently, while BGs are defined as constellations of nominally independent constituent firms subordinate to the strategic control of an ultimate owner (Granovetter, 1995, p. 95), they are synonymous with relational contracting schemas that govern and regulate social and economic transactions between and within them. Consequently, we emphasize, contrary to much of the prior literature (e.g., Khanna & Palepu, 2000; Khanna & Rivkin, 2001), that BGs should be viewed as integral to a wider network economy, with relational contracting schemas playing a central role in governance. Moreover, while the ultimate owners are heterogeneous, in ranging from entrepreneurs to corporate interests, to the state, or more typically families, the cultural resources they draw upon (e.g., Bhappu, 2000) emanate from the indigenous society's social fabric. This also underpins the powerful legitimacy claims accorded to BGs and the relational contracting schemas regulating their activity.

The importance of such relational contracting schemas and networks is profound in terms of their provision of a socially legitimate blueprint of appropriate means of engagement. By being relevant between BGs and other actors within an economy, as well as within the groups themselves (Barnett et al., 2013), these contracting schemas provide an institutionalized means of both enabling and constraining socially appropriate interactions amongst BGs and should be

viewed as synonymous with them. The schemas are centered on social trust (Barnett et al., 2013) in an individual's credibility. They enable contractual exchanges of resources with others in the network, defined by their personal track record, as well as those of their immediate and extended family and their clan, ethnic lineage, or tribal group. Moreover, they are centered on mutual reciprocity and on the intertemporal exchange of favors (Berger et al., 2015), where future exchanges are guaranteed based on reciprocity for exchanges in the current period. A proliferation of such mutually reciprocal exchanges over time is a powerful underpinning of social trust and shared norms between actors. Importantly, such relational contracting schemas are upheld through the threat of social ostracism of actors who breach contractual terms and/or expropriate their transacting partners (Granovetter, 1973; Greif, 2012). The threat of such ostracism effectively constitutes a positive externality, in reinforcing the wider network and the BGs that function within it.

The preceding arguments emphasize the inherent association between BGs and overarching social networks prevalent in emerging economies where BG interactions are assumed to be governed by relational contracting schemas emanating from the indigenous society's social fabric. BGs are therefore synonymous with network types of corporate governance (Vissa et al., 2010). Moreover, while BGs may benefit from quasi-monopolies and a concentration of wealth and economic opportunities at a national level (Young et al., 2008), at the same time, they coexist with one another in a competitive yet inherently collaborative system. Importantly, interactions among BGs entail the ultimate owners acting in a more intercessory or intermediary capacity, in competitively seeking to acquire resources into their BGs for further internal redistribution (Young et al., 2008). On balance, this implies a more benevolent scheme of engagement among BGs, resulting in a relatively equitable coordination or intermediation of capital or resources at a national level. These traits of a collaborative network economy, which is more typical of emerging economies, emphasize the prominent role of BGs, with their acquisition and intermediation of capital or resources being both enabled and constrained by culturally imbued relational contracting schemas. We argue this constitutes a powerful and opaque indigenous network-orientated corporate governance system, centered on BGs.

Contrastingly, Anglo-American corporate governance is embedded within international investment norms that have evolved from within the socio-cultural framework of the United States and the United Kingdom. Following Mair and Marti (2009), we define institutions as “multifaceted, durable social structures, made up of symbolic elements, social activities and material resources” resistant to change and transmitted across generations (Scott, 2001, p. 49). We argue that, following the demise of the Cold War, the far-reaching reforms across emerging economies, including those of Africa, were precipitated by state-led intervention (Joireman, 2001, 2004). Nascent states used their pre-existing European colonial heritage in fostering institutional complementarities and synergies with macroeconomic trading and economic associations based on European institutional frameworks (Joireman, 2004). States' attainment of legitimacy from these macroeconomic institutional arrangements is essential to their

attraction of foreign investment and funding, which supplements domestic savings–investment schedules (Tobin, 1982). Moreover, the necessity of states' attainment of international legitimacy exerts a powerful institutional pressure to replace isomorphic conformity of national regulatory frameworks and accompanying architecture with international norms of “best practice” (Haxhi & Aguilera, 2017). This has led indigenous states to initiate and influence the establishment of new national securities exchanges, as well as to reform existing financial institutions. These initiatives have exerted isomorphic pressures for conformity with “best practice,” within subordinate national economies (Haxhi & Aguilera, 2017). We argue that this development of the national formal institutional architecture involves the balancing of opposing claims of legitimacy at an international level, versus those at a local indigenous level (e.g., Aguilera et al., 2018). The local indigenous legitimacy is essential for the formal architecture to be assimilated within the national cultural context (e.g., Nakpodia et al., 2020). Moreover, indigenous legitimacy is accorded through the social networks that transcend the public-private sector boundaries of the economy (e.g., Liedong et al., 2023). This pattern underscores the influence of powerful local actors such as boundary-spanning BGs, beyond that of “lobbying” (e.g., Khanna & Rivkin, 2001) highlighted in prior literature. Therefore, while national polities may be demographically narrow and dominated by an empowered social elite (North, 1990, 1991, 1994), at the same time, they are permeated by extensive social networks and powerful indigenous legitimacy claims, centering on BGs and family. Such powerful legitimacy claims of BGs and their ability to transcend formal institutional architecture underscore their capabilities in acquiring additional external capital to supplement that internally available within the group.

2.1 | Hypotheses

Constituent firms of a BG may undertake an IPO on national securities exchanges for a variety of reasons, such as to widen the distribution of their ownership, to attain domestic political legitimacy, or to raise new external financial capital (e.g., Areneke et al., 2022; Areneke & Kimani, 2019). Importantly, all these motivations entail the firm seeking to improve outside investors' perceptions of its value (e.g., Adegbite, 2015) in an environment dominated by high uncertainty and informational asymmetry. Consequently, it is imperative for firms to demonstrate their ability to conform with investors' expectations, including those regarding corporate governance (Certo, 2003; Sanders & Boivie, 2004). The governance mechanisms adopted hinge not only on enhancing regulatory and economic efficiency but also on perceptions of the firm's legitimacy in the capital markets where the IPO in question takes place (Carruthers & Kim, 2011). In this way, firms are motivated to adapt their corporate governance to conform with the international investment norms within which the Anglo-American corporate governance model is inextricably embedded.

However, indigenous firms are confronted with isomorphic pressure to conform with the opaquer network corporate governance model (e.g., Liedong et al., 2023) prevalent within emerging

economies. Such constituent firms within a BG possess “linkage legitimacy” (Bitektine, 2011, p. 156), or legitimacy based on the firms' linkages with the BG overall, which constitutes a powerful legitimate social actor in its environment (Deephouse & Suchman, 2008). Constituent firms with higher BG ownership are more central within the BG network and therefore subject to powerful legitimacy claims emanating from the indigenous society's cultural fabric. This emphasizes conformity with the network's corporate governance model. Such higher BG ownership also implies an elevated importance of the constituent firm within the extended BG constellation of firms in terms of an enhanced intermediary and intercessory role in the acquisition and subsequent coordination of capital (Masulis et al., 2011). This is reflective of the ultimate owners of the BG having a higher direct ownership stake, thereby putting more of their wealth at potential risk rather than relying on indirect methods, such as pyramiding and cross shareholdings, to exacerbate control vis-à-vis cash flow ownership (Morck et al., 2005). Together, these arguments allude to higher BG ownership being associated with increased conformity with opaque indigenous network corporate governance, mirrored in the shunning or reduction of conformity with the Anglo-American model. To sum up, we propose the following hypothesis:

Hypothesis 1. BG ownership is negatively associated with a constituent firm's degree of adoption of Anglo-American corporate governance.

2.2 | Contingencies related to tribalism

Tribal and ethnic lineages owe their distinctive origins and powerful underlying social cohesiveness to the common genealogical and ancestral origins of members, where these are reinforced through consanguineous marriages and social interdependencies. These social ties reinforce notions of common identity, patronage, and loyalty to the tribal or ethnic lineage (Greif & Tabellini, 2010). Conversely, disciplining of behavioral infringements involves social exclusion and disenfranchisement (Greif, 2012), with an individual's consequent loss of access to social and economic resources. Such tribal or ethnic lineages constitute the basis for expansive social networks with powerful claims to underlying social legitimacy, which strongly impact business relations within nascent societies.

Based on institutional theory, we predict that higher tribalism is associated with a warping of the otherwise equitable and benign relational contracting system. This system emphasizes a balance between inward tribal loyalties and outward benevolence toward others within the clan or tribal-based system. Amplification of these loyalties is reflected in a transition from benign benevolence to nepotism and favoritism (Berger et al., 2015; Liedong et al., 2023). Moreover, such warped relational contracting systems tend to show durability despite largely superficial reforms aimed at countering such corruption (Heidenreich et al., 2015). We also expect national polities to be demographically narrower and more dominated by social elites drawn from the dominant ethnic lineage(s) with hegemonic control

(North, 1994). This will be reflected in national polities that are more predatory in nature (North, 1994), emphasizing extraction of economic rents by elites in accordance with their privileged social status.

This pattern has two important implications for BG constituent firms. The first is that national factor and resource markets are almost entirely subverted under the hegemonic control of elites (Hearn & Filatotchev, 2019) drawn from a handful of empowered ethnicities within a predatory polity (e.g., Liedong et al., 2023). Given correspondingly high levels of cronyism, nepotism, and favoritism embodied in institutionalized corruption (Heidenreich et al., 2015), these form impenetrable barriers, inhibiting political and social lobbying for access to resources. This pattern underscores a necessity to acquire resources, including capital, from external, predominantly international, resource markets.

The second is that—given the extremely demographically skewed nature of highly tribal polities (e.g., Greif, 2012; North, 1991, 1994), with these polities hegemonically controlled by one or a handful of nepotistic tribal lineages—their associated state bureaucracy and formal institutional architecture almost wholly lack wider social legitimacy. Consequently, BGs and their constituent firms are forced to seek legitimacy from external resource markets that adhere to the international system of investment norms within which the Anglo-American corporate governance model is embedded (e.g., Areneke et al., 2022). This too facilitates access to additional resources to supplement meager domestically available resources, including funding.

Conversely, for societies with low tribalism, we predict that relational contracting systems will retain their essentially benevolent character, with the associated society's institutional fabric being intermediary and intercessory in nature (Barnett et al., 2013). Therefore, the state bureaucracy and formal institutional architecture transplanted from the former European colonial era are more easily assimilated and absorbed within the society since it is markedly less prone to hegemonic “capture” by the vested interests of one or a handful of ethnicities (Hearn & Filatotchev, 2019). State bureaucracy essentially supplants the pre-existing indigenous institutional architecture (Nunn & Wantchekon, 2011) in adopting a more benign, intermediary role in the equitable distribution of resources and resolution of potential conflicts. This more intermediary character of assimilated state and formal architecture is at least comparable to the impartiality of its original design, this being philosophically centered on European definitions of property rights (Nunn & Wantchekon, 2011). BG

constituent firms would be anticipated to seek legitimacy and resources more from domestic resource and factor markets, these falling under the control of the state, which is altogether more equitable in its distribution of economic opportunities and resources. Moreover, these firms are also subject to the influence of more equitable intermediary social networks, with these networks exerting isomorphic pressures toward the adoption of opaque indigenous network-centered corporate governance (e.g., Aguilera et al., 2018). Consequently, there is less imperative to solicit capital from external capital markets and so a markedly lower need to adopt Anglo-American corporate governance practices. Our theoretical arguments lead us to propose, for firms in emerging economies, the following *tribalism moderation hypothesis*.

Hypothesis 2. The negative association between the BG's ownership of a constituent firm and that firm's degree of adoption of Anglo-American corporate governance practice is positively moderated by tribalism.

To summarize our theoretical arguments, we propose a contingency model with a base effect and moderating effect, as outlined in Figure 1.

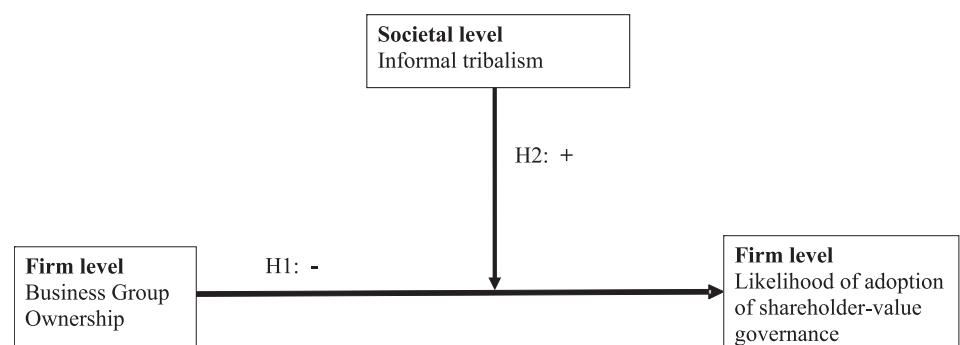

3 | DATA

The unit of analysis of our study is a firm undertaking an IPO in an African economy. We chose to study IPO firms since transparency and reporting are much stronger in such firms in a region characterized by generally underdeveloped financial markets and related institutions.

The dataset was constructed in three stages. After omissions of the national stock exchanges of Libya, Angola, Lesotho, Gabon, Somalia, and Sudan owing to a lack of listings during the sample time-frame or their indefinite closure, we then compiled a list of IPOs between January 2000 and August 2016, as identified in a comprehensive selection of African markets. Our primary source here was the national stock exchanges and their associated websites. This resulted in a preliminary population of 380 stock listings.

At the second stage, to ensure that our population covered IPOs and not private placements, the IPO prospectuses were obtained. The

FIGURE 1 Theoretical associations.

IPOs included at this stage were offerings that produced a genuine diversification of ownership among a base of minority shareholders (as opposed to private placements involving the preferential allocation of stock with institutional or corporate block holders in pre-arranged quantities and prices). Equally, care was taken to avoid misclassifications of registrations, introductions and seasoned (secondary) offerings, as these are often also officially referred to as IPOs. Furthermore, IPOs are defined as offerings of ordinary shares with single class voting rights, that is, excluding preferred stock, convertibles, unit and investment trusts, as well as readmissions, reorganizations and demergers, and transfers of shares between main and development boards. As a result of these efforts to solely focus on IPOs, our final population was reduced to 276 genuine IPO firms.

In the third stage, we focused on domestic private-sector firms, which led to the exclusion of state privatizations and joint ventures, whose governance structures are quite different from those of conventional firms. Notably, both observations from Cameroon were omitted at this stage, since both were joint venture entities between the state and a foreign MNE, their listings in effect being privatizations. This brought the total number of genuine private-sector IPOs down to 201.

Finally, we experienced missing values in terms of published age or year of IPO firm establishment in the prospectuses of eight firms, missing values for the number of shares issued to foreign investors for two firms, and missing executive tenure values for a further two firms. Missing values reduced the final sample to 189 IPOs, which formed the basis of the empirical analysis. The 12 missing observations were evenly distributed through the sample.

Data on IPOs were collected from the financial market regulator websites, prospectuses, third party websites, stock exchanges and from direct contact with IPO firms. These sources are listed in Table A1.

4 | METHODOLOGY

4.1 | Dependent variable

To focus on Anglo-American corporate governance, we have developed a new firm-level index, adapted from the provisions outlined in the New York Stock Exchange manual (NYSE, 2016). This is formed from the average of 16 elements (see Tables 1 and A2), which are identified from each individual firm's listing prospectus. All elements are binary coded, with the final 16th element relating to nonexecutive director independence and equaling one if at least one independent nonexecutive director is present on the board. The final index ranges from zero to one.

The choice of the 16 elements is based on the adaptation of the provisions relating to minority shareholder welfare, or Anglo-American corporate governance, as outlined in the New York Stock Exchange manual. Critical limitations regarding the viability of more detailed shareholder value indices include the indigenous cultural aptitude toward the adoption of such corporate governance

elements, which are costly to firms and typically lack deeper resonance or cultural compatibility. This is exemplified by culturally based concerns over detailed communication of individual director and managerial compensation and personal ownership of firms, as well as inhibitions toward financial contracts such as options and derivatives, with the latter scarcely existing anywhere across Africa and the Middle East. Moreover, there is a wholesale lack of regulated financial derivatives markets and pension scheme coverage in most emerging economies, which curtails governance elements relating to executive compensation and some golden parachute and poison pill anti-takeover provisions. Also omitted are clauses related to mechanisms such as greenmail, which are a reflection of the significantly less developed capital markets and weaker regulation prevalent in emerging economies. All elements are based on a corporate governance model underpinned by third party, arm's length contracting.

These contextual inhibitions of firms' adoption of Anglo-American corporate governance elements are visible in Table 2. The table allows a regional comparison of the average adoption of each of the 16 corporate governance elements comprising the new index, across South Africa, the continent's biggest economy, neighboring states in Southern Africa, a combination of East and West African subregions, and North Africa. Firms located in North Africa have the least adoption of any of the corporate governance elements, while those in South Africa have the highest, with those in Southern Africa having the next highest adoption rate. This mirrors the dominance of families, as well as cultural inhibitions toward external, arm's length contracting, emanating from a prevalence of Islamic shari'ya across North Africa. Conversely, South Africa's economy is the continent's largest and also the most outwardly integrated with the global economy, underscoring its susceptibility to isomorphic influences emphasizing conformity with the dominant Anglo-American governance and tenets of external contracting. There are equally pervasive differences in the adoption of Anglo-American corporate governance between firms located in English common law and those in civil code law jurisdictions, with the former generally having higher adoption rates across all 16 elements. Given the lack of effective reforms since original colonial-era transplantation, we argue these differences are fundamentally reflective of the differences in legal philosophy underpinning common versus civil code law. The former notably provides greater protections of minority rights vis-à-vis the state or dominant block owners, while the opposite is true of the latter.

The construction of our firm-level index addresses a number of shortfalls.¹ Much of the prior literature on shareholder rights relates to the anti-director index developed in the seminal work of La Porta et al. (1998). However, that index is restricted to provisions in the overarching national legal codes as opposed to relating to individual firms. More recently, to address this shortfall, Gompers et al. (2003) introduced the "G-index," comprised of 24 governance provisions, of which only 22 were firm level. A further limitation of that index is that it only applies to the US setting. Our construction of a shareholder rights index introduces a parsimonious construct that captures the protection of minority owners' property rights within a much broader remit of emerging and developing economies.

TABLE 1 Elements of firm level shareholder value governance.

Element	Formal		Informal	
	High inst. quality %	Low inst. quality %	High tribalism %	Low tribalism %
(1) Presence of non-ordinary shares	1.03	0.96	0.00*	2.13
(2) Proxy voting	78.35	72.12	73.83	76.60
(3) International auditor	42.27***	21.15	25.23**	38.30
(4) International accounting standards	45.36*	36.54	36.45*	45.74
(5) CEO pay disclosure	63.92***	47.12	37.38***	75.53
(6) Executive stock options	9.28**	2.88	3.74*	8.51
(7) Executive bonuses	22.68	17.31	14.02***	26.60
(8) Executive ownership	41.24	43.27	41.12	43.62
(9) Unitary Board	57.73*	50.00	52.34	55.32
(10) CEO = Chairperson	48.45*	40.38	36.45***	53.19
(11) Remuneration committee	29.90**	18.27	19.63*	28.72
(12) Remuneration committee independence	21.65**	11.54	12.15**	21.28
(13) Audit committee	51.55	51.92	56.07*	46.81
(14) Audit committee independence	34.02	30.77	31.78	32.98
(15) Attendance statement of nonexecutives	19.59*	12.50	3.74***	29.79
(16a) Independent nonexecutives >1 nonexecutive board member	49.48	48.08	50.47	46.81
(16b) Independent nonexecutives >50% of total nonexecutives	34.02**	23.08	24.30*	32.98
Index—shareholder value (>1)	44.65***	37.68	37.15***	45.48
Index—shareholder value (>50%)	43.69***	36.12	35.51***	44.61
Formal institutional quality	—	—	39.34***	56.16
Informal tribalism	57.01***	71.91	—	—

Note: This table outlines the individual corporate governance elements we have included which when combined form an index reflecting the relative degree of adoption of shareholder value corporate governance by each firm. We propose two shareholder value adoption indices. Both are essentially the same and contain 16 elements—bar for a difference in the last or 16th element relating to independent nonexecutive directors. The first index variant comprises the first 15 elements plus element 16a; namely, it takes the value 1 if there is a presence of at least one independent nonexecutive director on the board. The second index variant similarly comprises the first 15 elements though this time with element 16b, which takes the value 1 if there is a minimum of 50% of independent nonexecutives on the board. The indices were compiled by the authors from individual IPO listing prospectuses for all IPOs that took place in Africa between January 2000 and August 2016. Two *t*-difference in means tests are undertaken across the sample reflecting a division in corporate governance per high versus low formal institutional quality and then per high versus low informal tribalism. In terms of formal institutional quality, “high” is differentiated from “low” by those values over a median of 64%, while in terms of informal tribalism, “high” is differentiated from “low” by being over a median of 46.84%.

*** $p \leq 0.01$.

4.2 | Explanatory variables

Our study uses the percentage cash flow ownership, by BGs and their affiliates, in IPO firms, as the main effect outlined in Hypothesis 1. This is in line with studies such as Hu et al. (2019). Following Masulis et al. (2011), we trace ultimate owners and then define a BG as two or more nominally independent firms under the control of a common ultimate owner. The tracing of ultimate owners involves both consideration of direct lines of ownership and indirect and more opaque lines of indirect control, evidenced by a common family identity or extensive use of mutually interlocking directorates. This involves

detailed perusal of a variety of additional information sources, as outlined in Table A2, in order to fully appreciate the often-complex evolution of firms, their interlinkages, and their varying degrees of dependency on a family or entities such as the state. Such depth of consideration is essential given the more opaque lines of control within often expansive BGs that may also have had transitions in their ultimate owners, such as the 2008 takeover of Malian Bank of Africa group by Morocco's Benjelloun family, or that of the expansive group centered on former Tunisian premier Ben Ali and spouse Trabelsi by the Tunisian state. The complexity of the former, namely, Bank of Africa group, is demonstrated in Figure 2, which shows this BG

TABLE 2 Summary of governance elements.

Governance element	Type	Percentage (%) of firms with governance provisions in:						
		South Africa (a)	North Africa (b)	Sub-Saharan Africa (ex SA)		All Africa		Overall

Number of constituent firms		10	90	15	86	86	115	201

Note: This table presents the percentage of firms with each provision, classified per regional universe, where these are subdivided into South Africa, the continent's largest economy and equity market, and then Southern Africa excluding South Africa, North Africa, and the sub-Saharan (SSA) regions of East and West Africa, where these are subdivided between common law, civil code law, and overall for the year 2016. Overall is defined as the whole sample of firms. All data are sourced from listings prospectuses, as outlined in Table A1. a, b, c, and d refers to *t*-difference in means for each element in respect to other regional universes. So, for example, an "a" in the North Africa column refers to *t*-difference in means between North Africa (denoted as b) and South Africa (denoted as a). These are referred to in the context of *t*-difference in means test for each of the respective governance elements between each of the regions, with a *p* value of 0.10 or lower. In the *t*-difference in means comparison between common law and civil code law countries, the following relates to statistical significance of *p* values.

**p* ≤ 0.10.

***p* ≤ 0.05.

****p* ≤ 0.01.

dominating financial sectors of indigenous economies across the continent. Such identification is consistent with prior BG literature (e.g., Khanna & Palepu, 2000; Khanna & Yafeh, 2007; Singh & Gaur, 2009).

As a robustness measure, we also adopt the ratio of BG representatives on the board of directors of the constituent firm since a

prominent feature of BGs is control rights in excess of cash flow ownership entitlements. This measure provides a means to circumvent thorny issues in the family literature, where there is a general reliance on the definition of a family-controlled firm as being at a threshold percentage of ownership, typically 20%, or more liberally 10%, with such a restrictive definition failing to take account of wedges between

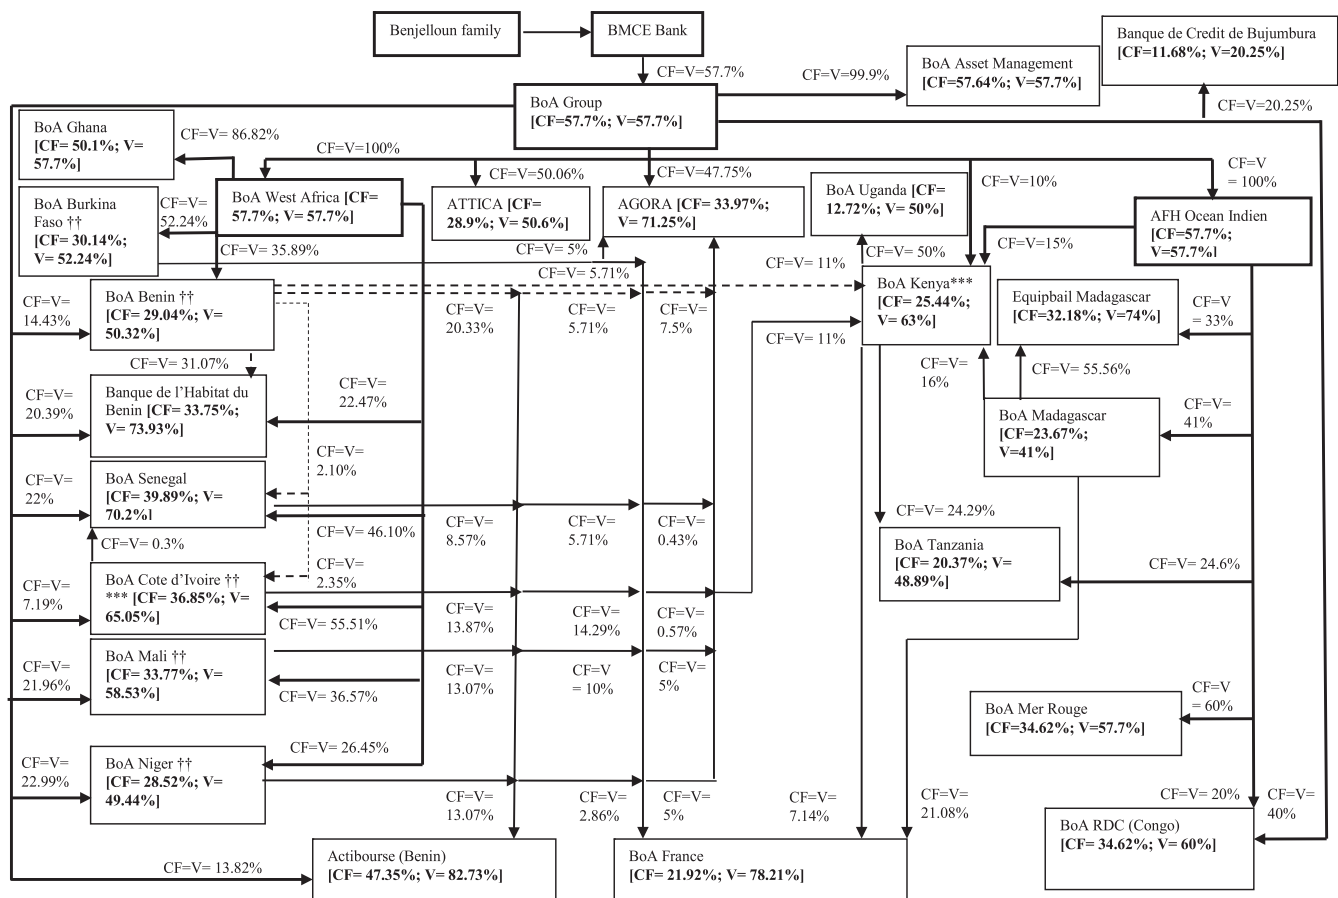

FIGURE 2 Extent of control of Bank of Africa business group, 2011. This traces the cash flow ownership versus control rights across Bank of Africa Group. Control and cash flow rights were estimated using the method outlined in Chernykh (2008). AGORA and ATTICA are entities located in the country of Benin that act as intra-group private equity within the internal capital market. *** and †† denotes investment by AGORA and ATTICA, respectively.

direct ownership and control. This is particularly pertinent given our focus on the contrast between direct and indirect pyramidal financing strategies and a sliding scale of direct cash flow ownership in relation to progressively elevated control being central to our theoretical model.

4.3 | Moderating variable

We follow Kim et al. (2004) in moderating our main association by an index. Our moderating index is that of tribalism, as originally developed by Jacobson and Deckard (2012). It is built upon five variables and centered and normalized to mitigate the potential effects of collinearity. It corresponds to Hypothesis 2. The tribalism index is defined below in expression (2):

$$\text{Tribalism} = \text{Corruption measure} + 0.5 * \text{Ethnic fractionalization} + 0.5 * \text{Indigenous population} + 2 * \text{Gender equality} + \text{Group grievance} \quad (2)$$

Jacobson and Deckard (2012) attribute the weights (as in the “2” or “0.5”) of each variable in conjunction with the relative importance of the variable in constituting “tribalism,” which in aggregate is scaled from 0 (lowest) to 1 (highest). They argue that, as the internal reliability of the scale is high, shifting the weightings of specific variables within the index does not significantly change the rankings of individual nations or meaningfully alter its ability to predict the dependent variable in models (Jacobson & Deckard, 2012, p. 10). The five constituent variables are defined as follows.² The first, *corruption*, is measured by the corruption perceptions index of Transparency International, which measures survey participants’ perceptions of corruption. Corruption mirrors the impact of nepotism, favoritism, and cronyism in preferentially facilitating transfers between kinship, clan, and tribal groups.

The second variable is *ethnic fractionalization*, which is defined as in expression (3):

$$\text{Ethnic Fractionalization}_i = 1 - \sum_{j=1}^N s_{ij}^2 \quad (3)$$

where s_{ij} denotes the proportion of the total population of group i in country j and N denotes the total number of groups in the population. The measure scores 0 in a perfectly homogeneous population and reaches its theoretical maximum value of 1 when an infinite population is divided into an infinite number of groups of one member. The measurement of ethnicity is fraught with complexity. Alesina et al. (2003) provide a comprehensive list of sources for ethnicity data, along with the assumptions used in its interpretation and then subsequent inclusion in the preceding expression (3) for fractionalization. The first comprehensive attempt to develop a metric effective worldwide was undertaken in 1964 by a team of Soviet ethnographers and documented in *Atlas Narodov Mira* (Fearon, 2003; Luiz, 2015). This metric formed the basis of ethnic fractionalization used in Easterly and Levine's (1997) study of how ethnicity constrained African development. It was subsequently updated in 2001 by Encyclopaedia Britannica and formed the basis of a Herfindahl index of ethnic diversity used in Fearon (2003) and the metrics of ethnic, linguistic, and religious fractionalization developed by Alesina et al. (2003). Alesina et al.'s fractionalization measures, as used in this study, were developed using definitions presented by Encyclopaedia Britannica and augmented by the CIA World Factbook, World Directory of Minorities, and national census data.

The third variable is *indigenous population*. This mitigates sensitivity in the measurement of ethnic fractionalization owing to its contingency on the level of ethnicity. This is exemplified by countries such as the United States and Canada having quite high diversity scores comparable to countries such as Pakistan and sub-Saharan Africa (SSA). However, the tribalism metric circumvents these issues through an additional term capturing the proportion of *indigenous population*. Indigenous populations in the United States and Canada are relatively low, in contrast to those in Pakistan and SSA for example, which substantially reduces their tribalism scores (see Table A3).

The fourth variable is *gender equality*. This utilizes the gender gap index, which covers four subunits of inequality: economic participation and opportunity, educational attainment, health and survival, and political involvement. Disparities between countries worldwide are relatively minimal in terms of education and health but rise significantly in terms of labor force participation and earnings, as well as political participation. Gender inequality is central to tribalism inasmuch that male gender roles provide security while their female counterparts are defined by the notion of reproduction of family, kin, and culture.

The fifth and final variable is *group grievance*, which notably has double the weight of both the ethnic fractionalization and indigenous population variables. This is sourced from the group grievance index, which is 1 of 10 constituents of the Fund for Peace's Fragile States Index.³ Jacobson and Deckard (2012, p. 9) argue "... the variable captures the history of aggrieved communal groups, public scapegoating of those groups with or without nationalistic political rhetoric, any patterns of atrocity committed with impunity or with support or participation of government groups and institutionalized political exclusion." Conceptually, it is linked to anthropological "balanced opposition" where the fear of violence in tribal societies between

kinship groups paradoxically acts as a fundamental organizing principle (Jacobson & Deckard, 2012). This acts to reinforce a spectrum of loyalties from tight-knit immediate familial units to extended family, clans, and ultimately ethnicity, where social ties are vulnerable to rival familial, clan, or tribal interests (Jacobson & Deckard, 2012). Group grievance formally captures such tribal rivalries in operationalizing a variable rather than relying on assumptions regarding motivations for conflict. This advances the preceding Reynol-Querol (RQ) measure of polarization. That measure focusses on a smaller number of tribal groups making up larger fractions of a population, where the smaller number of groups provides greater incentive for conflict (Montalvo & Reynal-Querol, 2005).⁴

Together, these variables capture influences on the political economy from tribalism. This marks an improvement over and a significant departure from solely considering the more static measure of ethnic fractionalization. This way, a number of yet unresolved complexities in measuring culture have been avoided. First of these complexities is the assumption that dimensions need to be mathematically orthogonal to one another (e.g., Hofstede's four-dimensional measures have recently been augmented by a further two dimensions; see Beugelsdijk et al., 2017). Conceptually, this is problematic since cultural dimensions are often interrelated in institutionally pluralist settings (Tung & Stahl, 2018), where this interrelatedness stems from complementarities within institutional frameworks. Mathematically, this interrelatedness causes additional problems connected to the measurement of institutional, psychic, and cultural "distance" between countries (Beugelsdijk et al., 2018; Tung & Stahl, 2018). This relates to the common method of measuring distance in Euclidean terms between aggregated mean points formed from orthogonal dimensions in Cartesian statistical space (Beugelsdijk et al., 2018; Cuypers et al., 2018).⁵

Second, and by far the most profound complexity and criticism of existing representations of cultural dimensional measurement, is the notion of multiple cultures existing within notional "national" boundaries (Tung & Stahl, 2018). This too has been argued to contribute to serious constraints in the application of existing cultural measurement techniques, as well as related distance metrics, owing to the risk of spurious estimations (Luiz, 2015). However, this emergent literature has so far been limited to the introduction of ethnic fractionalization measures and the elaboration of their elevated explanatory power in explaining a range of macroeconomic, political and social outcomes (e.g., Alesina et al., 2003; Fearon, 2003).

As a descriptive exercise, these variables are displayed per market across the African sample in Table 3. There are some notable observations. The first is that ethnic fractionalization is extremely low across North Africa, yet extremely high across much of SSA. While these extreme differences in diversity have been cited previously (e.g., Moscana et al., 2017; Nunn & Wantchekon, 2011), this reveals a critical limitation in the universal application of measures based on ethno-linguistic fractionalization. Contrastingly, this extreme variation is offset by the generally high gender inequality, which has a double weighting, and to a lesser extent by the lower weighted measures of corruption, the proportion of population that is indigenous and group

TABLE 3 Summary of governance, institutional quality, and investor protection statistics.

Note: This table reports summary statistics for average direct BG ownership, shareholder value governance adoption, formal institutional quality, informal tribalism, and all the precursor indices forming tribalism for individual sample markets.

grievance. The extremely high ethnic fractionalization in SSA, alongside the extreme variation throughout Africa, including North Africa, also underscores the utility of the region for testing new measures whose efficacy is based on their generalizability.

4.4 | Control variables

We adopt four sets of control variables. Our first set is *Environmental controls*, consisting of two variables. One is a binary effect accounting for English common law jurisdictions as opposed to their civil code law counterparts. This variable accounts not only for documented differences in legal and juridical philosophy between the two overarching legal families—with common law emphasizing jurisprudence while civil code relies on state legislators and “bright line” rules—but also for more reaching cultural differences, whereby civil code parallels the Dirigiste (state-led) capitalist model. In the African context, civil code law includes both the French and Portuguese legal systems. As our second environmental control variable, we control for income and wealth inequalities through the inclusion of the natural logarithm of a jurisdiction's GDP per capita, denominated in US\$.

Board controls account for firm-level variations. The first is logarithmically transformed board size, defined as the total number of both nonexecutive and executive directors, which accounts for size-related differences in board communication and effectiveness in decision making as well as free riding (Boyd, 1994), while at the same time accounting for the need to accommodate more diverse environmental contingencies through the co-optation of directors, such as those from the extended family and important stakeholders (Khanna & Yafeh, 2007). Our second board control variable is the logarithmically transformed average executive tenure, which accounts for entrenchment effects impinging on optimality in executive risk taking and decisions. The third variable is the board independence ratio—defined as the proportion of independent nonexecutives on the board, which accounts for the separation between nonexecutives and their executive counterparts in terms of optimal monitoring (Jensen & Meckling, 1976). The fourth variable is a binary effect, accounting for the entrepreneurial founder being retained as CEO as opposed to their succession having been initiated. This accounts for the longevity of the founder's investment horizon and the upper-echelon culture-setting altruism of the founder, together with their social capital derived through personal networks acting as a critical resource for the firm (Hearn & Filatotchev, 2019). The fifth variable is the ratio of directors drawn from social elites within indigenous political economies to total board size. This captures the degree to which indigenous social elites have been co-opted on to the board of directors (e.g., North, 1991, 1994). They are defined as those with senior roles in government, commerce, and civil society and sourced from the director biography sections of annual reports.

Firm controls are drawn from prior empirical governance studies (Finkelstein & Boyd, 1998; Sanders & Carpenter, 1998). As our first firm control variable, we use the natural logarithm of a firm's pre-tax

revenues (or sales) as a proxy for size, assumed to control for the complexity of the firm's operations and thus mirroring the complexity of the task environment, in turn reflective of an enhanced need for the adoption of shareholder value governance in order to successfully cope with increasing information-processing requirements and complexities in decision making. As our second firm control variable, we adopt the accounting return on assets (ROA) as a measure of firm performance, in line with Finkelstein and Boyd (1998). As our third variable, we control for firm age, with older firms anticipated to have larger, more complex operations mirroring more complex task environments. It also accounts for the “liability of newness” and the considerable information asymmetries generated by a lack of operational and performance history (Arthurs et al., 2008). As our fourth firm control variable, we adopt a capital control, the ratio of debt to total assets, which is the total long- and short-term liabilities divided by the total asset value of the firm and provides a measure of the gearing or leverage of the employment of debt. This avoids potential issues in relating debt directly to equity, due to equity's variability over the business cycle (see Bruton et al., 2010).

Finally, we adopt *IPO controls*. Our first IPO control variable is the ratio of shares offered at IPO to total shares issued and outstanding (e.g., Hearn & Filatotchev, 2019), both obtained from the appendices of financial statements. This captures the costs in public flotations of shares (Ritter, 1987). It also captures the degree of dilution in insider ownership and control during the IPO process and accounts for the diversification of the ownership structure of the firm, which necessitates increased governance protections for minority property rights. Our second IPO control variable is a binary effect accounting for whether the lead manager handling the listing process is foreign, which accounts for the lead manager's familiarity with overseas regulatory regimes and awareness of minority property rights protections through shareholder value governance adoption.

4.5 | Empirical model

To test our hypotheses, we adopt pooled OLS models with random effects applied to the cross-section (between firms). Three regression models are estimated. The first model only contains controls. The second solely has as an explanatory variable the proportion of BG ownership, with this corresponding to an empirical test of Hypothesis 1. The third corresponds to our moderating hypothesis, concerning the interaction of tribalism and BG ownership in explaining the degree of adoption of shareholder value corporate governance—which is the subject of our Hypothesis 2.

We do not include country binary fixed effects since their addition would lead to perfect collinearity with both formal institutional quality and the common law binary legal control. This way, we avoid falling into the dummy variable trap (Wooldridge, 2009).⁶ Industry and time (year) fixed effects are applied across all models. Industry definitions vary by country, while compliance with ISIN and SEDOL industry category codification is not universal across the continent, reflecting the underdeveloped nature of financial institutions.

Consequently, we follow Khanna and Rivkin (2001) in handling similar issues; that is, we adopt Bloomberg's basic industry definitions.⁷ Errors are cluster-robust in terms of countries.

5 | EMPIRICAL RESULTS

5.1 | Bivariate analysis

Correlations (in Table 4) between variables are low and statistically insignificant for the most part. Further inspection of the variance inflation factors for all independent variables reveals that all are below 10, while the mean variance inflation factor for all independent variables together is 2.89 and mitigates concerns over multicollinearity (Vittinghoff et al., 2012). However, in order to mitigate concerns over our institutional index being included in models twice during the moderation of the independent variables, it is centered and normalized. The variance inflation factors for both institutional quality and the tribal index are acceptable, being below 10.

5.2 | Multivariate analysis

The empirical evidence regarding the *main effect* is detailed in model 2 (in Table 5). There is a large, negative, and statistically significant association (-0.076 , $p = 0.040$) between BG ownership and the (non) adoption of Anglo-American corporate governance. This strongly supports Hypothesis 1. It has economic significance too, with a one percentage point change in BG ownership leading to a 7.6% decrease in Anglo-American corporate governance adoption.

Our evidence regarding the moderation of our main effect by tribalism can be seen in model 3. Here, the main effect between BG ownership and shareholder value governance adoption (-0.076 , $p = 0.038$) is positively moderated by informal tribalism ($+0.061$, $p = 0.052$). This supports Hypothesis 2. In terms of economic significance, the moderation causes the main effect to be offset by the firm being located in a high (as opposed to low) tribal framework. This leads to a one percentage point change in BG ownership causing a 7.6% decrease in Anglo-American corporate governance, on the one hand, to be partially offset in magnitude by a 6.1% increase in Anglo-American governance adoption contingent on the percentage level of tribalism present within the local informal institutional framework in which the firm is embedded.

The empirical evidence regarding the association of the controls with the dependent variable is consistent across all models. In terms of institutional controls, a firm's adoption of shareholder value governance is associated with higher formal institutional quality, common law jurisdictional heritage, and higher GDP per capita. There is only one significant association between the board controls and the dependent variable; a higher ratio of nonexecutives on a board is associated with a higher adoption of shareholder value governance. In terms of firm controls, shareholder value governance adoption is associated with higher firm gross revenues, indicative of greater

complexity of task environments and a necessity to adopt formalized governance structures in order to attain legitimacy in various differentiated product markets. In terms of IPO controls, counterintuitively, shareholder value governance adoption is associated with a lower dispersion of shares offered in proportion to total shares outstanding. This may be explained by deep-seated inhibitions over dilution of control and detrimental conflict being introduced into the firm through "conflicting voices" of minority owners, empowered by shareholder welfare protections in the firm's own governance framework. Finally, firms adopt more shareholder value governance when the lead managers assisting in their flotations are foreign, which emphasizes the importance of isomorphic conformity and pragmatic legitimacy, associated with appropriate notions of governance in international capital markets.

The diagnostic statistics associated with all four models reveal there is a consistent increase in overall adjusted R^2 explanatory power, as well as in the Wald χ^2 statistics, from model 1, which considers controls only, to the progressive addition of, first, BG ownership (model 2), then its moderation by tribalism (model 3). This observation provides support for the strength of the effects of both formal institutional quality and tribalism as moderators of the association between BG ownership and the BG constituent firm's shareholder value governance adoption.

As a final support for our findings, using model parameter estimates, we provide in Figure 3, a three-dimensional probability surface with respect to the likelihood of shareholder value governance adoption. Figure 3 visualizes the moderating role of tribalism. At higher levels of tribalism, increasing BG ownership is associated with increasing adoption of shareholder value or Anglo-American governance, while the opposite is true in progressively lower tribalism contexts.

5.3 | Supplementary and robustness tests

We undertake two supplementary analyses in order to further substantiate our main findings. The first supplementary analysis involves re-running our regression models using Alesina et al.'s (2003) ethnic as well as linguistic fractionalization metrics as substitutes for our original use of a tribalism metric. The resulting coefficients are comparatively small in size and lack statistical significance. The second involves moderation of the main effect by worldwide governance indicators (WGI) formal institutional quality, and the resulting interactive coefficient is negative, is statistically significant, and has the opposite sign to that for tribalism. We disaggregate the WGI measure into its six dimensions, which are recursively included in the moderation, and find those with statistically significant interactive coefficients are government effectiveness, regulatory quality, rule of law, and democratic voice and accountability. Both supplementary tests support our findings.

Next, we undertake five robustness tests to verify our initial results. The *first* involves a revised Anglo-American index, where we replace the binary condition of at least one independent nonexecutive director being present on the board with an alternative that there be a

Note: This table presents the random (country) effects OLS regression results for dependent variable which is the shareholder value governance index (>1). In all cases, the formal institutional quality and informal tribal indices are normalized. Additional country-level constant is included in variable part of random variance component.

^aBinary effects for year and industry were included in the models but are not reported in the table.

^bStandard errors are in parentheses.

^cCountry-cluster adjusted standard errors and covariance.

minimum proportion of 50% of independent nonexecutive directors on the board. The *second* involves replacing BG ownership with the ratio of BG representation on the board of directors and applying random effects OLS regressions, where we obtain qualitatively identical results. The *third* involves creating four equally sized ordinal categories for Anglo-American governance adoption. We repeat this exercise twice to account for the two different Anglo-American governance indices, as outlined in the preceding first step. At this stage, we undertake three series of tests, with a variety of empirical models, and find all empirical results to be in line with those of our original analysis. The *fourth* involves a hierarchical linear Poisson count model, which

addresses shortcomings in terms of informational loss in probit models and potential alternative modeling specifications arising from our dependent variable. The results using both variants of the Anglo-American index and both BG ownership and the ratio of BG representatives on the board of directors largely corroborate all of our prior results from the main analysis. The *fifth* and final robustness test involves our omitting any countries/markets with less than five IPO firms from our sample. This implies the dropping of markets such as Sierra Leone, Malawi, Mozambique, and Namibia, which have very few IPO firm observations and these often not having any BG involvement. The resulting subsample comprising only the more populous

FIGURE 3 Business group ownership and moderation by informal tribalism. [Colour figure can be viewed at [wileyonlinelibrary.com](https://onlinelibrary.wiley.com/doi/10.1111/cege.12547)]

markets contains 171 IPO firms, which then form the basis of our re-estimation of all our models. The empirical results from these provide further support for our main analysis, with coefficients that have stronger statistical significance (even lower p values). Taken together, all five robustness tests support our original findings.

6 | DISCUSSION

This study is motivated by a lack of corporate governance research incorporating the latent cultural factors shaping emerging economy firms. Specifically, we address African firms' propensity to adopt Anglo-American corporate governance. We also motivate this research by the fact that Anglo-American corporate governance is embedded within international capital markets or investment norms. Our approach subscribes to the view that the corporate governance of a firm is essential in defining a firm's strategic orientation, in terms of its seeking to attain goals. These goals are the acquisition of external capital, accompanied by conformity in corporate governance with, and legitimacy from, a given institutional framework. We focus on BGs, which are ubiquitous in emerging economies and especially across Africa and Middle Eastern regions. Our argument is that BGs capitalize on formal institutional voids, in conjunction with the powerful influence of indigenous cultural institutions, predominantly centered on extended family.

Our findings advance a conceptualization of the life cycle of firms (see Brav & Gompers, 2003) within emerging economies. We propose a single major juncture—the transit from indigenous relational

contracting and network reliance to externally seeking funds from unrelated providers. Importantly, this is reflected in the duplicity evident within many emerging economies, between informal cultural institutions and typically incongruous formal institutional architecture. The former is overwhelmingly powerful in providing the social fabric within which all economic relations and actors are embedded. This also includes the formal institutional architecture which—while retaining its European heritage—is at least partially assimilated within the indigenous social fabric. This pattern leads to the visible bifurcation existing in many emerging economies and especially those of Africa and the Middle East.

Our application of institutional theory addresses shortcomings in the traditional agency approaches prevalent in prior literature (e.g., Masulis et al., 2011; Morck et al., 2005). Specifically, we address the association between a BG's ownership of constituent firms and these firms' propensity to acquire external supplementary capital. Such agency-based approaches view decreasing BG direct ownership of a constituent firm as associated with an increase in its riskiness, which necessitates supplementary, externally sourced finance and resources. This is conceptualized by an increase in the riskiness of a BG-constituent firm being accompanied by a need for these risks to be borne by outside, unrelated investors, while the BG itself should ideally leverage elevated indirect control over the focal BG constituent firm. Contrastingly, our findings corroborate our theoretical arguments that increased BG ownership of a given constituent firm is associated with the elevated importance of that firm within the BG's network, with this akin to the firm seeking increased legitimacy from the wider BG. Given the BG's embeddedness within the cultural

foundation of a country, this implies elevated cognitive legitimacy from opaque indigenous corporate governance and therefore lower adoption of Anglo-American shareholder value governance—which is essential to the attraction of outside, unrelated investors.

We also challenge the neoclassical and agency-based literature that has emphasized the adoption of Anglo-American corporate governance as a means to enhance firm efficiencies and productivity (e.g., Coffee, 2001). Likewise, we challenge the corporate governance convergence thesis by questioning the progressive transition and convergence of national corporate governance regimes into a globally dominant Anglo-American model. Our institution-theoretic legitimacy-based view emphasizes—in line with Luo et al. (2009)—the importance of corporate governance as a means for a given firm to seek conformity with a particular institutional framework in order to secure access to external capital essential for its survival. Our view is accommodative of heterogeneity both between and within national boundaries—something visible across emerging economies as well as their developed counterparts. Our approach also accounts for the significant variation in firm-level corporate governance and the often-overlooked influence of the underlying cultural heritage of countries in determining firm-level corporate governance adoption.

Our consideration of the cultural heritage of countries extends to the impact of cultural fragmentation, through the sociological lens of tribalism, on BG constituent firms' degree of adoption of Anglo-American shareholder value corporate governance. We address a shortcoming in the use of static measures such as ethnic fractionalization, by introducing a more dynamic theorization of tribalism, or cultural fractionalization, through the contortion or warping of relational contracting schema. Our approach emphasizes the institutionalized nature of relational contracting schema, their contextual embeddedness within indigenous social networks and the huge cognitive legitimacy accorded to them. This usefully accounts for high tribalism contexts, being culturally fragmented, with a detrimental warping of relational contracting schemas to emphasize in-group favoritism and nepotism. This in turn detrimentally impacts incentive structures within the “national” social and cultural fabric, leading firms subject to higher BG control to be increasingly reliant on external capital, given the significant impediments to being able to contract relationally and gain social trust within the indigenous cultural context. Similarly, our theorization based on relational contracting schemas also accounts for low tribalism contexts that beneficially lack the fragmented favoritism of their high tribal counterparts, with relationships being more intercessory and intermediary in character. Such traits lead to a more equitable system of resource distribution across a national economy and importantly support formal institutional architecture tasked with the equitable redistribution of resources nationally. Here, BG constituent firms focus on resource acquisition and seeking legitimacy from informal cultural frameworks, implying lower Anglo-American shareholder value governance adoption. Our findings are of particular importance given the proliferation of subnational fault lines in the form of tribal and ethnic lineages across many emerging economies and especially those of Africa and the Middle East. Furthermore, we highlight a parsimonious linkage between the institutional fabric of a given

nation-state and firms' relative adoption of formal Anglo-American corporate governance. In doing so we address a common shortfall in emerging markets research as it typically focuses on the impact of formal institutional frameworks or more static, overarching national definitions of culture.

Theoretically, our findings address shortfalls in prior literature that have largely focused on how interactions between institutions and organizational factors might shape adoption of Anglo-American corporate governance norms (e.g., Westphal & Graebner, 2010; Westphal & Zajac, 2001), where this has not focused on the nature of these interactions across distinct national institutional contexts. This shortfall has limited scholarly understanding of why firms seek to avoid adopting international investment norms based on Anglo-American corporate governance. We highlight how African firms' choice of corporate governance is contingent on underlying institutional and cultural foundations within the society's social fabric. With this lacuna in mind, we advance a theoretical perspective focused on the actor-centered model of corporate governance, where rival actors draw on political power from within the underlying institutional context. This perspective has a profound outcome in shaping the managerial discourse and the corporate governance model adopted by the firm.

The managerial implication of our findings is that “culture matters” for choice of corporate governance. This implies that management and boards should focus on the dynamic measure of cultural integrity embodied in the concept of tribalism, rather than static measurements of institutional distances between homogeneous national cultures. In particular, rather than being a static construct, communitarian culture is “operationalized” through institutionalized relational contracting systems, which form the basis for tribalism. We argue tribalism not only captures unidimensional ethno-linguistic fractionalization but also mirrors the potential institutionalized corruption associated with it. Managers and boards are then better able to execute firm strategy through the selective adoption of Anglo-American governance, depending on the specific external constituencies whose resources are preferentially sought. In this way, they are faced with a trade-off between conformity with indigenous institutional frameworks and the need for increased legitimacy from their foreign counterparts in order to circumvent constraints in the national context.

Our study has limitations that offer opportunities for further research. The first is that it only considers IPO firms, as publication of firm data is argued to be better in flotation documents. However, the study should benefit from being extended to a longitudinal perspective. As a second suggestion for further research, it would be valuable, data limitations notwithstanding, to also extend our study across all African listed firms, as well as emerging economies worldwide.

7 | CONCLUSIONS

Our findings emphasize that the degree of national tribalism should be considered when analyzing the firm-level adoption of corporate

governance in Africa. The study underpins the importance of considering rival environmental contingencies in emerging market contexts, when organizations in general and BGs, in particular, seek supplementary external funding.

We argue that a high level of tribalism impedes the efficient coordination of resources within indigenous economies. Moreover, it requires BG constituent firms that seek external funding to accommodate Anglo-American corporate governance in order to conform with international investment norms. Specifically, the interdependence of formal institutional architecture and tribalism—both fundamentally associated with the demographic shape and with the incentive structures embedded within the underlying national political economy—calls for careful considerations when policymakers are formulating national corporate governance recommendations.

ACKNOWLEDGEMENTS

We would like to thank Professors Konstantinos Stathopoulos and Till Talaulicar, the editors-in-chief. We are especially grateful to Professor Niels Hermes, the assigned editor to this manuscript, and two anonymous reviewers for their valuable comments and suggestions that significantly improved this research. An earlier version of this research was awarded best paper prize in “International Finance, Accounting & Corporate Governance” track of European International Business Conference, Milan, Italy, December 2017.

CONFLICT OF INTEREST STATEMENT

The authors declare that they have no conflict of interest with respect to the research reported in this paper.

NOTES

¹ Constructing such a firm-level index is labor intensive and involves unrestricted access to all prospectuses for each firm at listing, which are typically unavailable or at best partially available through standard subscription third-party data vendors such as Bloomberg or Thomson. Further complexity, as evidenced in our African multi-country sample, is added by the prevalence of at least four languages in the corporate communications and filings, two different accounting philosophies (continental European versus Anglo Saxon), and the often at best minimal adoption of formal international accounting standards such as IFRS.

² Jacobson and Deckard (2012, p. 10) argue that, as the internal reliability of the scale is high, shifting the weightings of specific variables within the index does not significantly change the rankings of individual nations or meaningfully alter its ability to predict or moderate the role of BG ownership in determining a firm's Anglo-American governance adoption.

³ See <https://fragilestatesindex.org/indicators/c3/>.

⁴ A shortcoming of this RQ measure is that, while it accounts for examples of conflict such as that in Rwanda and Burundi between rival Tutsi and

Hutu groups, it fails to account for unrest in regions such as Nigeria's Niger Delta, Eastern Kenya following the 2007 elections, and North-Western Pakistan, these latter three regions being defined by considerable ethno-linguistic fractionalization.

⁵ Off-diagonal covariances between dimensions increase the spuriousness of this simple distance method, necessitating more complex and less tractable techniques for gauging distance.

⁶ If dummy variables for all country (and time) categories were included, their sum would equal one for all observations, which would be identical to and hence perfectly correlated with the vector-of-ones variable whose coefficient is the constant term; if the vector-of-ones variable was also present, this would result in perfect multicollinearity, so that the matrix inversion in the estimation algorithm would be impossible. This is referred to as the dummy variable trap (Wooldridge, 2009).

⁷ The industry classifications are basic materials, consumer goods non-cyclical, consumer goods cyclical, energy, financials, health, industrials, technology, telecommunications, and utilities. The identification of firms according to their industry using broad Bloomberg definitions is in keeping with the data limitations across our sample, a common characteristic of emerging economies.

AUTHOR BIOGRAPHIES

Bruce Hearn is a Professor of Accounting & Finance at the University of Bradford and a Professor (Visiting) at University of Southampton. His research focusses on corporate finance and corporate governance in emerging economies and has been published in journals such as *Journal of Corporate Finance*, *Journal of World Business* and *Journal of Business Venturing*.

Lars Oxelheim is a Professor of International Business and Finance at the School of Business and Law, University of Agder, Norway, and Professor Emeritus at Lund University, Sweden. He is an Honorary Professor at the Fudan University, Shanghai, founding chairman of the Swedish Network for European Studies in Economics and Business (SNEE), and affiliated to the Research Institute of Industrial Economics (IFN), Stockholm. Lars Oxelheim's research interests are in the area of the interplay between the

firm and its macroeconomic environment encompassing economic and financial integration as well as managerial aspects, corporate governance and risk management. He has published some 50 books and a number of articles in journals like *Journal of International Business Studies* and *Journal of World Business*.

Trond Randøy is a Professor of Corporate Governance at Copenhagen Business School, and part-time affiliated with the University of Agder. He has published more than 50 scholarly articles in journals such as *Journal of International Business Studies*, *Journal of Business Venturing*, *Entrepreneurship Theory and Practice*, and *Journal of World Business*. He is currently an editor with *Corporate Governance: An International Review*. Randøy values

the interaction with business practice, and he is currently serving on five corporate boards, of which two firms are publicly listed (MTI Investment SE and Sparebanken Sør) and three are private.

How to cite this article: Hearn, B., Oxelheim, L., & Randøy, T. (2023). The impact of indigenous culture and business group affiliation on corporate governance of African firms. *Corporate Governance: An International Review*, 1–25. <https://doi.org/10.1111/corg.12547>

South Africa	Websites: Johannesburg stock exchange [JSE] (https://www.jse.co.za/)

Note: This table documents a non-exhaustive representation of data and information sources from across Africa.

TABLE A2 Elements of firm level shareholder value governance.

Element	Definition
Separation of ownership from control	
(1) Presence of non-ordinary shares	Binary 1/0 variable. Takes value of 1 if firm exclusively uses ordinary (one share one vote) shares across entire shareholder base. Thus, there is no discrimination between shareholders through the use of non-voting stock, preference shares, convertible instruments, or share structures inferring differentials in voting rights—such as A, B, and C class shares.
(2) Proxy voting	Binary 1/0 variable. Takes value of 1 if a clear statement is made in listing prospectus regarding recognition and arrangements for voting by proxy.
(3) International auditor	Binary 1/0 variable. Takes value of 1 if either an international auditor or its local subsidiary is used as the firm's auditor.
(4) International accounting standards	Binary 1/0 variable. Takes value of 1 if firm declares that its accounts and financial statements were prepared in accordance with international (as opposed to indigenous) accounting standards. These are typically GAAP, US GAAP, or IFRS.
Incentive compensation	
(5) CEO pay disclosure	Binary 1/0 variable. Takes value of 1 if CEO salary is disclosed in listing prospectus. This relates to improved transparency with external investors (principals) and a reduction in their bonding costs.
(6) Executive stock options	Binary 1/0 variable. Takes value of 1 if firm remunerates its executives with stock options or other derivative instruments.
(7) Executive bonuses	Binary 1/0 variable. Takes value of 1 if firm remunerates its executives with performance-related bonus payments at end of tax year.
(8) Executive ownership	Binary 1/0 variable. Takes value of 1 if executives are entitled to stock ownership as part of their compensation arrangements.
Board monitoring	
(9) Unitary board	Binary 1/0 variable. Takes value of 1 if the board of directors is unitary, that is, if it is comprised of a single tier encompassing executive and nonexecutives.
(10) CEO = chairperson	Binary 1/0 variable. Takes value of 0 if the same individual occupies both the roles of CEO and chairperson and 1 otherwise
(11) Remuneration committee	Binary 1/0 variable. Takes value of 1 if the firm established a remuneration committee as part of its governance apparatus—where this committee exclusively decides compensation levels and structure of board membership.
(12) Remuneration committee independence	Binary 1/0 variable. Takes value of 1 if the remuneration committee is independent (in terms of membership) from CEO or other dominant block shareholders.
(13) Audit committee	Binary 1/0 variable. Takes value of 1 if the firm established an audit committee as part of its governance apparatus—where this committee is solely responsible for the firm undertaking audits of its activities and for ensuring these audits are performed by external independent auditors.
(14) Audit committee independence	Binary 1/0 variable. Takes value of 1 if the audit committee is independent (in terms of membership) from CEO or other dominant block shareholders.
(15) Attendance statement of nonexecutives	Binary 1/0 variable. Takes value of 1 if the firm declares either an Attendance Rota of nonexecutives in designated board meetings (essential to their performing their monitoring function within the firm on behalf of external principals) or a clear statement that attendance is checked and duly reported to external shareholders.
(16a) Independent nonexecutives > 1	Binary 1/0 variable. Takes value of 1 if there is at least one independent nonexecutive on the board.
(16b) Independent nonexecutives > 50% of total nonexecutives	Binary 1/0 variable. Takes value of 1 if a minimum of 50% of nonexecutives are independent and unaffiliated with CEO or any external shareholder principal.

Note: This table outlines the governance elements we have included as an integral part of the shareholder value firm level governance structure. Each element is defined alongside its source. All indices are equally weighted arithmetic averages of constituent elements. There are two overall or aggregate indices denoting a firm's adoption of shareholder value governance—where the distinction between the two is based on (1) the presence of at least one independent nonexecutive director on the board or (2) a minimum of 50% of independent nonexecutives on the board. The indices were compiled by the authors from individual IPO listing prospectuses for all IPOs that took place in Africa between January 2000 and August 2016.

TABLE A3 Worldwide comparison of indices.

	WGI Aggregate	Tribalism Index
North America		
Canada	0.90390	0.25000
United States	0.80588	0.25000
